Appendix C

Risk Assessment Review of COU, POU, and OU3

This page intentionally left blank

C1.0 Introduction

This appendix presents the methodology for reviewing and evaluating changes to chemical and radiological risk assessment parameters that took effect during this FYR period and details the results of the risk assessment evaluation. The methodology used for this evaluation is based on the methodology used for the comprehensive risk assessment (CRA) completed in 2006. The CRA included a human health and ecological risk assessment for the COU and POU; a separate risk assessment was completed for OU3 (DOE 1997). A summary of the CRA may be found in the Third FYR report (DOE, 2012) and the complete CRA is found as an appendix to the RI/FS Report (DOE 2006).

The changes to risk assessment factors were evaluated for the COU, POU, and OU3 to determine if these changes have an impact to the risks presented by residual contamination left on site. Although the POU and OU3 have been deleted from the National Priorities List (NPL), a review of changes to risk assessment factors is required to determine if the UU/UE designation is still valid at both OUs

C2.0 Central and Peripheral Operable Units

In the RI/FS Report (DOE 2006), the nature and extent of residual contamination in soil and sediment were evaluated after completion of the RFCA accelerated actions. Each nature and extent of contamination evaluation identified analytes of interest (AOIs). AOIs are chemicals that have been detected at concentrations that may contribute to the risk to future receptors. The evaluation studied the extent of sitewide contaminants and evaluated which chemicals remained after the completed accelerated actions. The soil AOIs identified in the RI/FS Report are presented in Table C-1.

In 2006, a comprehensive risk assessment was completed for the Rocky Flats Site to quantify the risk of residual contamination remaining after accelerated cleanup actions at the site (DOE 2006). The CRA was conducted in accordance with the EPA- and CDPHE-approved *Comprehensive Risk Assessment Work Plan and Methodology* (DOE 2005c). Calculations and conclusions in the CRA were based on post-remediation data; that is, data collected after the completion of all RFCA accelerated actions. To facilitate the CRA, the Site was divided into the twelve exposure units (EUs) shown in Figure C-1. The basic methodology for conducting human health risk assessments, as described in the *Risk Assessment Guidance for Superfund* (EPA 1989), has not changed since the CRA was completed.

C2.1 Risk Definitions

This section presents the definitions of key risk terms used throughout this appendix.

95 percent upper confidence limit (95UCL): This is statistical upper bound estimate of the mean for a set of samples and is a conservative measure of the average concentration. As a general rule, EPA recommends use of the 95UCL as the exposure point concentration for soils at a site (EPA 2002).

PRELIMINARY DRAFT FOR WORKING GROUP REVIEW (Not edited) [DATE \@ "M/d/yyyy"]

Cancer risk: Presents the added probability of an individual or population of developing cancer during a lifetime as a result of exposure to site contaminants. The acceptable risk range for CERCLA sites is an added risk of less than 1 in 1,000,000 (1×10^{-6}) to a maximum of 1 in 10,000 (1×10^{-4}).

Hazard quotient: The ratio of the exposure level of a single substance to an acceptable noncarcinogenic toxicity value. If multiple substances are present, hazard quotients are summed in a hazard index. For CERCLA sites, the maximum acceptable hazard index is 1.0.

Maximum detected concentration (MDC): Maximum concentration detected in any soil sample a given constituent and exposure unit.

Table C-1. Soil AOIs identified in the RI/FS

Surface Soil (0–0.5 ft)	Subsurface Soil (0.5–8 ft)	Subsurface Soil (>8 ft)

C2.2 CRA Review Methodology

As an initial step in the CRA process, residual concentrations of constituents in soil for each EU were compared to preliminary remediation goals (PRGs) developed for a wildlife refuge worker (WRW). The PRGs represent concentrations for individual chemicals that would equate to a carcinogenic risk of 1×1^{-6} or a noncarcinogenic hazard quotient of 0.1 based on the exposure assumptions for the WRW. The 2006 CRA used a hazard quotient of 0.1 as an initial, conservative screening level; a hazard quotient of 1.0 is the maximum permissible limit. The PRGs were developed using toxicity data that were current at the time of the CRA and were developed for exposures to both surface and subsurface soils. PRGs for subsurface soils are higher than those for surface soils as it was assumed that the exposure frequency would be much lower (20 days per year compared to 230 days per year). The MDC for each detected constituent at each EU was compared to its respective PRG. If the MDC was less than the PRG, the constituent was eliminated from further consideration. If the MDC exceeded the PRG, the 95UCL of the mean for that constituent was compared to the PRG. If the 95UCL was less than the PRG, the constituent was eliminated from further consideration. If the 95UCL exceeded the PRG, the constituent was further evaluated based on frequency of detection, comparison to background concentrations, and professional judgement. Constituents passing through these remaining screening criteria were identified as COCs for each EU (Table C-2) and were further evaluated in the CRA. (Note that the sitewide AOI screening process and CRA EU-specific COC screening process were somewhat different and produced different results.) In the 2006 CRA, COCs were only identified for surface soils. All constituents in subsurface soils were eliminated by the 95UCL screen and no quantitative risks were calculated.

						Exposi	ıre Unit

Table C-2, Surface Soil COCs Identified for Each EU in the CRA

C2.3 FYR Risk Assessment Review Methodology

Because the first two steps of the COC screening process in the CRA relied on a comparison of residual soil concentrations with the WRW PRGs, any subsequent changes to exposure assumptions or toxicity values used to calculate the PRGs could change the outcome of the screening process. For this FYR risk assessment review, a methodology similar to that described

[&]quot;X" = constituent was designated a COC in the 2006 CRA.

[&]quot;- " = constituent was not designated a COC in the 2006 CRA.

PRELIMINARY DRAFT FOR WORKING GROUP REVIEW (Not edited) [DATE \@ "M/d/yyyy"]

above for the CRA was applied to determine the impact of changes to risk assessment parameters for surface soils. Figure C-2 presents the screening methodology. In lieu of recalculating site-specific PRGs for a WRW, this FYR evaluation utilized the EPA regional screening levels (RSLs) for industrial soil as a proxy for revised WRW PRGs. The RSLs incorporate current toxicity data and methodologies for the same exposure pathways of concern for the WRW. The default exposure assumptions for the industrial soil scenario are very similar to those used for the WRW for surface soils. Table C-3 compares the key assumptions used in RSL and site-specific PRG calculations. Where exposure factors are not the same, those used by EPA tend to be more conservative (i.e., assume a greater degree of exposure). Therefore, it was determined that the EPA industrial soil RSLs were an acceptable screening tool to represent updated surface soil WRW PRGs (referred to as "updated WRW RSLs" for the remainder of this appendix).

The complete list of surface soil PRGs developed for the CRA were compared to the updated WRW RSLs (EPA 2016). Of the more than 200 original PRGs that were evaluated, slightly more than half were higher than the updated values. The vast majority of the lower RSL values were organic chemicals and many are considered to be volatile organic compounds (VOCs). EPA has recently finalized guidance on vapor intrusion (EPA 2015) and as a result has updated information on many VOCs included in their RSL tables. Additionally, the EPA approach to evaluating risks for the inhalation pathway was finalized in 2009. The methodology used in the CRA reflects older guidance for estimating exposures for this pathway. It is likely that a combination of these factors explain why such a large number of the PRGs are higher than current RSLs. Decreases for most constituents were within an order of magnitude, but RSLs for a few constituents are several orders of magnitude lower than PRGs (e.g., cyclohexane).

Where PRGs were lower than current RSLs, it was assumed that results of the original screening process are still valid. Where RSLs were lower than PRGs, a rescreening of the EU statistical data was performed. EPA RSLs that were lower than PRGs were compared to data presented in the CRA for each EU. The analytical data (MDCs and 95UCL values) used in this FYR review are the same data used in the 2006 CRA; no new data was collected to support this FYR review. The MDCs and 95UCLs used in the surface soil screening were compared to the RSLs. If 95UCL data were not already tabulated, a 95UCL was calculated from statistical data provided in the CRA. If MDCs or 95UCLs were lower than the current RSLs, constituents were eliminated from further consideration. All other constituents were retained for further evaluation. Table C-4 presents the results of the chemical screening process by EU; Table C-5 summarizes the screening process by constituent name.

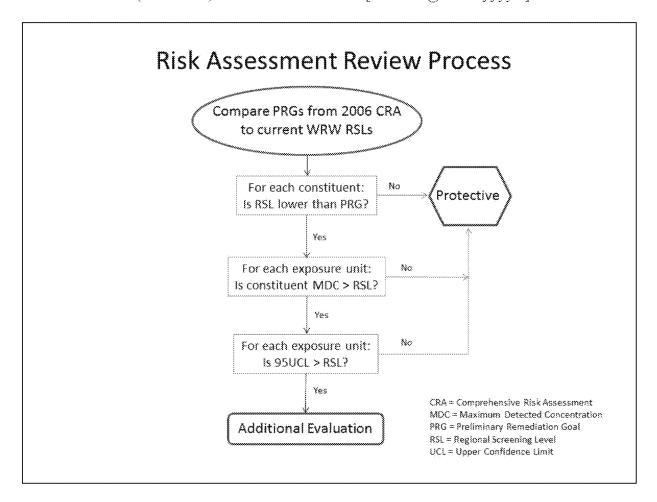

Figure C-2. Risk Assessment Review Process

Table C-3. Comparison of key exposure assumptions for RSLs and PRGs

Exposure Factor (units)	EPA RSL default value	WRW PRG assumption				
Frequency of exposure (days/yr)	250	Surface soils—230 Subsurface soils—20				
Exposure duration (years)	25	18.7				
Exposure time (hr/day)	8	8				
Soil ingestion rate (mg/day)	100	100				
Adult body weight (kg)	80	70				
Skin surface area (cm²)	3527	3300

Notes: First column lists all constituents for which WRW PRGs were developed. The constituents are arranged in the same order as they were in the CRA methodology document where the PRGs were developed (DOE 2004). The second column lists all constituents where the May 2016 EPA RSLs were lower than the WRW PRGs. The constituents are arranged in the order used in the PRG screening tables that were included in the CRA for each EU. That same order is used for subsequent columns. The third column includes all constituents that were carried through the screening process for any EU. The last column contains all constituents with a MDC that exceeded an EPA RSL. Note that arsenic and vanadium are not carried past the first column in this table because the EPA RSLs are greater than the WRW PRGs and rescreening isn't required.

Because no COCs were identified in the CRA for subsurface soils and because the reevaluation of surface soil data discussed above indicated that the CRA process was sound in identifying COCs, a more targeted approach was taken in this FYR to answer Question B with regard to subsurface soils. An abbreviated PRG list was used for subsurface soil screening based on the results of the surface soil screening process. This included all constituents for which any surface soil MDC exceeded the surface soil PRG (constituents listed in Table C-4 and last column in Table C-5); tetrachloroethene was also added to this list as it was identified as a subsurface AOI in the RI/FS (Table C-1). The constituents evaluated along with screening results are listed in Table C-6. The current WRW RSLs were multiplied by 11.5 to obtain current estimates of subsurface WRW PRGs. The screening with this smaller set of PRGs proceeded in the same manner as the surface soil FYR evaluation described above.

Table C-6. Subsurface Soil Chemical Constituent Screening Results by EU

Constituent	Industrial Area EU	Upper Woman Drainage EU	Wind Blown EU	No Name Gulch EU	Upper Walnut Drainage EU	Lower Woman Drainage EU	Rock Creek EU	Lower Walnut Drainage EU	Inter Drainage EU	West Area EU	Southwest Buffer Zone Area EU	Southeast Buffer Zone Area EU

[&]quot;X" indicates MDC > EPA RSL

Arsenic and vanadium were included in this table because they were identified as COCs in the CRA and 95UCL exceeds WRW PRG.

[Add Radiological Methodology]

In addition to human health risk calculations performed in the CRA, a radiation dose assessment for exposure to residual radionuclide contamination in surface soil and subsurface soil was also conducted. The dose assessment was conducted to demonstrate compliance with the annual dose limits in Colorado Radiation Control Regulations (Title 6 *Code of Colorado Regulations* 1007-1, Part 4 [6 CCR 1007-1, Part 4]), which was identified as an applicable or relevant and appropriate requirement (ARAR) in the RI/FS Report.

C2.4 Chemical Constituent Screening Results

Surface Soils. As was the case in the original CRA screening process, nearly all constituents were eliminated in this FYR evaluation based on the MDC comparison screen. Despite the lower EPA RSLs, the MDCs were typically much lower than the screening values. Very few constituents were retained by the RSL screen that were not also retained by the PRG screen. Among these is uranium, for which EPA has recently recommended a much lower toxicity value (EPA 2016). Most constituents passing the RSL screen were subsequently eliminated based on the 95UCL comparison or following additional evaluation (e.g., frequency of detection [<5 percent]). Of the constituents evaluated in this FYR evaluation screening process, only four constituents passed through the 95UCL screen. These are summarized in Table C-7.

Shaded boxes indicate 95UCL > EPA RSL

Table C-7. Chemical Constituents and EUs where 95UCL Exceeds Current Screening Level

		Exposure Unit											
Constituent	Industrial Area EU	Upper Woman Drainage EU	Wind Blown EU	No Name Gulch EU	Upper Walnut Drainage EU	Lower Woman Drainage EU	Rock Creek EU	Lower Walnut Drainage EU	Inter Drainage EU	West Area EU	Southwest Buffer Zone Area EU	Southeast Buffer Zone Area EU	
Arsenic	Χ		Х										
Vanadium													
2,3,7,8-TCDD		Х											
Benzo[a]pyrene	Χ	Х		Х	Х								
Diben[a,h]anthracene		Х											

[&]quot;X" means that the constituent would be considered a COC based on CRA screening methodology. Shaded boxes differ with the CRA results.

As in the original CRA, dioxin was identified as a COC for the Upper Woman Drainage EU (UWOEU) and benzo(a)pyrene as a COC for the Industrial Area EU (IAEU), UWOEU, and the Upper Walnut Drainage EU. Based on the rescreening process, benzo(a)pyrene would also be considered as a COC for the No Name Gulch EU, with concentrations slightly above the current RSL. The rescreening process also confirmed that arsenic is still considered a COC for the IAEU and Wind Blown EU based on current RSL concentrations; estimated risk levels associated with residual arsenic would be similar to that in the CRA. The arsenic 95UCL for all the other EUs also exceeded the PRG (and the current RSL) but arsenic was eliminated as a COC for those EUs in the CRA based on subsequent screens; it is assumed that the arsenic screening process is still valid for those EUs. Based on the current vanadium RSL, vanadium would not be a COC. The vanadium PRG is based on a lower toxicity value than is being used by EPA; however, vanadium PRG is based on a lower toxicity value could change in the future. As in the CRA, dibenz[a,h]anthracene did pass through the 95UCL screen for the UWOEU; however, the frequency of detection was less than 5% for this constituent and it was eliminated on that basis. For the most part, the rescreening process confirmed the results of the CRA.

Subsurface Soils. The MDCs for a number of constituents exceeded the revised PRG screening values. However, all constituents dropped out based on the 95UCL screen and the reevaluation confirmed that there are no subsurface COCs.

The vapor intrusion pathway was identified in the CRA as a potentially complete pathway for VOCs in subsurface soils, including those at depths greater than 8 feet. Most of the AOIs identified for subsurface soils in the RI/FS are VOCs (Table C-1). EPA has finalized guidance for evaluating the vapor intrusion pathway (EPA 2015) and has provided guidance for evaluating this pathway in during five-year reviews (EPA 2012c). Updated toxicity data are also available for some VOCs that are identified as AOIs at subsurface depths > 8 ft (e.g., tetrachloroethene, trichloroethene). However, institutional controls are in place at the COU that eliminate the vapor intrusion pathway by prohibiting the construction of habitable structures. RAOs and cleanup goals remain valid and are not affected by updated guidance and toxicity data as long as institutional controls remain in place.

In addition to the toxicity values discussed above, EPA is reviewing the toxicity of two COCs for the COU—arsenic and benzo(a)pyrene. The arsenic study suggests that current methods of estimating risks from arsenic due to soil ingestion likely overestimate actual risks. The EPA study of benzo(a)pyrene (EPA 2014) is not yet completed and results cannot be cited at this time. Changes in slope factors may be forthcoming, but are not yet available. None of these additional studies affect the protectiveness of the remedy.

C2.5 Radionuclide Screening Results

[Add radiological review results for COU and POU.]

C3.0 OU3

[Add Radiological review results for OU3; there will not be a chemical discussion since all COCs for OU3 were radionuclides]
